Single Particle Reconstruction using cryo-EM

Schematic drawing of the imaging process:

The cryo-EM problem:

Main Algorithmic Challenges

- 1 Orientation assignment
- 2 Heterogeneity (resolving structural variability)
- 3 **2D Class averaging (de-noising)**
- 4 Symmetry detection
- 5 Motion correction
- 6 Particle picking

Class Averaging in Cryo-EM: Improve SNR

Image denoising by vector diffusion maps

- Generalization of Laplacian Eigenmaps (Belkin, Niyogi 2003) and Diffusion Maps (Coifman, Lafon 2006)
- Introduced the graph Connection Laplacian
- S, Zhao, Shkolnisky, Hadani (SIIMS 2011)
- Hadani, S (FoCM 2011)
- S, Wu (Comm. Pure Appl. Math 2012)
- Zhao, S (J Struct. Bio. 2014)

Experimental images (70S) courtesy of Dr. Joachim Frank (Columbia)

Class averages by vector diffusion maps (averaging with 20 nearest neighbors)

Rotation Invariant Distances

- Projection images I_1, I_2, \dots, I_n with unknown rotations $R_1, R_2, \dots, R_n \in SO(3)$
- Rotationally Invariant Distances (RID)

$$d_{RID}(i, j) = \min_{O \in SO(2)} \|I_i - O \circ I_j\|$$

- Cluster the images using K-means.
- Images are not centered; also possible to include translations and to optimize over the special Euclidean group.
- Problem with this approach: outliers.
- At low SNR images with completely different viewing directions may have relatively small d_{RID} (noise aligns well, instead of underlying signal).

Outliers: Small World Graph on \mathbb{S}^2

- Define graph $G = (V, E)$ by $\{i, j\} \in E \iff d_{RID}(i, j) \leq \epsilon$.

- Optimal rotation angles

$$O_{ij} = \operatorname{argmin}_{O \in SO(2)} \|l_i - O \circ l_j\|, \quad i, j = 1, \dots, n.$$

- Triplet consistency relation – good triangles

$$O_{ij} O_{jk} O_{ki} \approx I_{2 \times 2}.$$

- How to use information of optimal rotations in a systematic way?
Vector Diffusion Maps
- “Non-local means with rotations”

Vector Diffusion Maps: Setup

In VDM, the relationships between data points (e.g., cryo-EM images) are represented as a weighted graph, where the weights w_{ij} describing affinities between data points are accompanied by linear orthogonal transformations O_{ij} .

Manifold Learning: Point cloud in \mathbb{R}^p

- $x_1, x_2, \dots, x_n \in \mathbb{R}^p$.
- Manifold assumption: $x_1, \dots, x_n \in \mathcal{M}^d$, with $d \ll p$.
- Local Principal Component Analysis (PCA) gives an approximate orthonormal basis O_i for the tangent space $T_{x_i}\mathcal{M}$.
- O_i is a $p \times d$ matrix with orthonormal columns: $O_i^T O_i = I_{d \times d}$.
- Alignment: $O_{ij} = \operatorname{argmin}_{O \in O(d)} \|O - O_i^T O_j\|_{HS}$
(computed through the singular value decomposition of $O_i^T O_j$).

Parallel Transport

- O_{ij} approximates the parallel transport operator
 $P_{x_i, x_j} : T_{x_j} \mathcal{M} \rightarrow T_{x_i} \mathcal{M}$

Laplacian Eigenmap (Belkin and Niyogi 2003) and Diffusion Map (Coifman and Lafon 2006)

- Symmetric $n \times n$ matrix W_0 :

$$W_0(i, j) = \begin{cases} w_{ij} & (i, j) \in E, \\ 0 & (i, j) \notin E. \end{cases}$$

- Diagonal matrix D_0 of the same size:

$$D_0(i, i) = \deg(i) = \sum_{j:(i,j) \in E} w_{ij}.$$

- Graph Laplacian, Normalized graph Laplacian and the random walk matrix:

$$L_0 = D_0 - W_0, \quad \mathcal{L}_0 = I - D_0^{-1/2} W_0 D_0^{-1/2}, \quad A_0 = D_0^{-1} W_0$$

- The diffusion map Φ_t is defined in terms of the eigenvectors of A_0 :

$$A_0 \phi_l = \lambda_l \phi_l, \quad l = 1, \dots, n$$

$$\Phi_t : i \mapsto (\lambda_l^t \phi_l(i))_{l=1}^n.$$

- Symmetric $nd \times nd$ matrix W_1 :

$$W_1(i, j) = \begin{cases} w_{ij} O_{ij} & (i, j) \in E, \\ 0_{d \times d} & (i, j) \notin E. \end{cases}$$

$n \times n$ blocks, each of which is of size $d \times d$.

- Diagonal matrix D_1 of the same size, where the diagonal $d \times d$ blocks are scalar matrices with the weighted degrees:

$$D_1(i, i) = \text{deg}(i) I_{d \times d},$$

and

$$\text{deg}(i) = \sum_{j: (i, j) \in E} w_{ij}$$

$A_1 = D_1^{-1}W_1$ is an averaging operator for vector fields

- The matrix A_1 can be applied to vectors v of length nd , which we regard as n vectors of length d , such that $v(i)$ is a vector in \mathbb{R}^d viewed as a vector in $T_{x_i}\mathcal{M}$. The matrix $A_1 = D_1^{-1}W_1$ is an averaging operator for vector fields, since

$$(A_1 v)(i) = \frac{1}{\deg(i)} \sum_{j:(i,j) \in E} w_{ij} O_{ij} v(j).$$

This implies that the operator A_1 transport vectors from the tangent spaces $T_{x_j}\mathcal{M}$ (that are nearby to $T_{x_i}\mathcal{M}$) to $T_{x_i}\mathcal{M}$ and then averages the transported vectors in $T_{x_i}\mathcal{M}$.

Affinity between nodes based on consistency of transformations

- In the VDM framework, we define the affinity between i and j by considering all paths of length t connecting them, but instead of just summing the weights of all paths, we *sum the transformations*.
- Every path from j to i may result in a different transformation (like parallel transport due to curvature).
- When adding transformations of different paths, cancelations may happen.
- We define the affinity between i and j as the consistency between these transformations.
- $A_1 = D_1^{-1}W_1$ is similar to the symmetric matrix \tilde{W}_1

$$\tilde{W}_1 = D_1^{-1/2}W_1D_1^{-1/2}$$

- We define the affinity between i and j as

$$\|\tilde{W}_1^{2t}(i,j)\|_{HS}^2 = \frac{\deg(i)}{\deg(j)} \|(D_1^{-1}W_1)^{2t}(i,j)\|_{HS}^2.$$

Embedding into a Hilbert Space

- Since \tilde{W}_1 is symmetric, it has a complete set of eigenvectors $\{v_l\}_{l=1}^{nd}$ and eigenvalues $\{\lambda_l\}_{l=1}^{nd}$ (ordered as $|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_{nd}|$).
- Spectral decompositions of \tilde{W}_1 and \tilde{W}_1^{2t} :

$$\tilde{W}_1(i, j) = \sum_{l=1}^{nd} \lambda_l v_l(i) v_l(j)^T, \quad \text{and} \quad \tilde{W}_1^{2t}(i, j) = \sum_{l=1}^{nd} \lambda_l^{2t} v_l(i) v_l(j)^T,$$

where $v_l(i) \in \mathbb{R}^d$ for $i = 1, \dots, n$ and $l = 1, \dots, nd$.

- The HS norm of $\tilde{W}_1^{2t}(i, j)$ is calculated using the trace:

$$\|\tilde{W}_1^{2t}(i, j)\|_{HS}^2 = \sum_{l,r=1}^{nd} (\lambda_l \lambda_r)^{2t} \langle v_l(i), v_r(i) \rangle \langle v_l(j), v_r(j) \rangle.$$

- The affinity $\|\tilde{W}_1^{2t}(i, j)\|_{HS}^2 = \langle V_t(i), V_t(j) \rangle$ is an inner product for the finite dimensional Hilbert space $\mathbb{R}^{(nd)^2}$ via the mapping V_t :

$$V_t : i \mapsto ((\lambda_l \lambda_r)^t \langle v_l(i), v_r(i) \rangle)_{l,r=1}^{nd}.$$

Vector Diffusion Distance

- The vector diffusion mapping is defined as

$$V_t : i \mapsto ((\lambda_l \lambda_r)^t \langle v_l(i), v_r(i) \rangle)_{l,r=1}^{nd}.$$

- The vector diffusion distance between nodes i and j is denoted $d_{\text{VDM},t}(i,j)$ and is defined as

$$d_{\text{VDM},t}^2(i,j) = \langle V_t(i), V_t(i) \rangle + \langle V_t(j), V_t(j) \rangle - 2\langle V_t(i), V_t(j) \rangle.$$

- Other normalizations of the matrix W_1 are possible and lead to slightly different embeddings and distances (similar to diffusion maps).
- The matrices $I - \tilde{W}_1$ and $I + \tilde{W}_1$ are positive semidefinite, because

$$v^T (I \pm D_1^{-1/2} W_1 D_1^{-1/2}) v = \sum_{(i,j) \in E} \left\| \frac{v(i)}{\sqrt{\deg(i)}} \pm \frac{w_{ij} O_{ij} v(j)}{\sqrt{\deg(j)}} \right\|^2 \geq 0,$$

for any $v \in \mathbb{R}^{nd}$. Therefore, $\lambda_l \in [-1, 1]$. As a result, the vector diffusion mapping and distances can be well approximated by using only the few largest eigenvalues and their corresponding eigenvectors.

Application to the class averaging problem in Cryo-EM (S, Zhao, Shkolnisky, Hadani 2011)

(a) Neighbors are identified using d_{RID}

(b) Neighbors are identified using $d_{VDM, t=2}$

Figure : SNR=1/64: Histogram of the angles (x -axis, in degrees) between the viewing directions of each image (out of 40000) and its 40 neighboring images. Left: neighbors are identified using the original rotationally invariant distances d_{RID} . Right: neighbors are post identified using vector diffusion distances.

Zhao, S J. Struct. Biol. 2014

- Naïve implementation requires $O(n^2)$ rotational alignments of images
- Rotational invariant representation of images: “bispectrum”
- Dimensionality reduction using a randomized algorithm for PCA (Rokhlin, Liberty, Tygert, Martinsson, Halko, Tropp, Szlam, ...)
- Randomized approximated nearest neighbors search in nearly linear time (Jones, Osipov, Rokhlin 2011)

The Hairy Ball Theorem

- There is no non-vanishing continuous tangent vector field on the sphere.
- Cannot find O_i such that $O_{ij} = O_i O_j^{-1}$.
- No global rotational alignment of all images.

Let $\iota : \mathcal{M} \hookrightarrow \mathbb{R}^p$ be a smooth d -dim closed Riemannian manifold embedded in \mathbb{R}^p , with metric g induced from the canonical metric on \mathbb{R}^p , and the data set $\{x_i\}_{i=1,\dots,n}$ is independently uniformly distributed over \mathcal{M} . Let $K \in C^2(\mathbb{R}^+)$ be a positive kernel function decaying exponentially, that is, there exist $T > 0$ and $C > 0$ such that $K(t) \leq Ce^{-t}$ when $t > T$. For $\epsilon > 0$, let $K_\epsilon(x_i, x_j) = K\left(\frac{\|\iota(x_i) - \iota(x_j)\|_{\mathbb{R}^p}}{\sqrt{\epsilon}}\right)$. Then, for $X \in C^3(T\mathcal{M})$ and for all x_i almost surely we have

$$\lim_{\epsilon \rightarrow 0} \lim_{n \rightarrow \infty} \frac{1}{\epsilon} \left[\frac{\sum_{j=1}^n K_\epsilon(x_i, x_j) O_{ij} X_j}{\sum_{j=1}^n K_\epsilon(x_i, x_j)} - X_i \right] = \frac{m_2}{2dm_0} \left(\langle \iota_* \nabla^2 X(x_i), e_l \rangle \right)_{l=1}^d,$$

where ∇^2 is the connection Laplacian, $X_i \equiv \left(\langle \iota_* X(x_i), e_l \rangle \right)_{l=1}^d \in \mathbb{R}^d$ for all i , $\{e_l(x_i)\}_{l=1,\dots,d}$ is an orthonormal basis of $\iota_* T_{x_i} \mathcal{M}$, $m_l = \int_{\mathbb{R}^d} \|x\|^l K(\|x\|) dx$, and O_{ij} is the optimal orthogonal transformation determined by the algorithm in the alignment step.

Example: Connection-Laplacian for S^d embedded in \mathbb{R}^{d+1}

The connection-Laplacian commutes with rotations and the eigenvalues and eigen-vector-fields are calculated using representation theory:

$$S^2 : 6, 10, 14, \dots$$

$$S^3 : 4, 6, 9, 16, 16, \dots$$

$$S^4 : 5, 10, 14, \dots$$

$$S^5 : 6, 15, 20, \dots$$

(a) S^2

(b) S^3

(c) S^4

(d) S^5

Figure : Bar plots of the largest 30 eigenvalues of A_1 for $n = 8000$ points uniformly distributed over spheres of different dimensions.

- The Graph Connection Laplacian

$$L_1 = D_1 - W_1$$

- The Normalized Graph Connection Laplacian

$$\mathcal{L}_1 = I - D_1^{-1/2} W_1 D^{-1/2} = I - \tilde{W}_1$$

- Averaging operator / random walk matrix for vector diffusion:

$$A_1 = D_1^{-1} W_1$$

- A Cheeger inequality for the graph connection Laplacian
(Bandeira, S, Spielman SIAM Matrix Analysis 2013)

More applications of VDM: Orientability from a point cloud

Encode the information about reflections in a symmetric $n \times n$ matrix Z with entries

$$Z_{ij} = \begin{cases} \det O_{ij} & (i,j) \in E, \\ 0 & (i,j) \notin E. \end{cases}$$

That is, $Z_{ij} = 1$ if no reflection is needed, $Z_{ij} = -1$ if a reflection is needed, and $Z_{ij} = 0$ if the points are not nearby. Normalize Z by the node degrees.

(a) S^2

(b) Klein bottle

(c) $\mathbb{R}P^2$

Figure : Histogram of the values of the top eigenvector of $D_0^{-1}Z$.

Orientable Double Covering

Embedding obtained using the eigenvectors of the (normalized) matrix

$$\begin{bmatrix} Z & -Z \\ -Z & Z \end{bmatrix} = \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix} \otimes Z,$$

Figure : Left: the orientable double covering of $\mathbb{R}P(2)$, which is S^2 ; Middle: the orientable double covering of the Klein bottle, which is T^2 ; Right: the orientable double covering of the Möbius strip, which is a cylinder.
